MRI Brain WWO IV Contrast

MRI of the Brain (Without and With Contrast) 2024 hours

Clinical Indication: Post concussion syndrome, F07.81.

Technique: T1-weighted images were acquired axially and sagittally from the foramen magnum to the vertex. Axial fast inversion-recovery, fast T2-weighted, and diffusion-weighted axial images were obtained, without contrast. Postcontrast axial and coronal images, with the uneventful intravenous administration of 15 mL MultiHance contrast.

Comparison: MRI brain March 2015.

Findings: SWI series demonstrates a few 1- to 3-mm hemosiderin foci from prior hemorrhage involving the left caudate head and bilateral frontal lobe cortical convexities as well as the mesial right temporal lobe. These appear similar to previous studies. No new foci of acute hemorrhage. No definite cortical encephalomalacia.

The ventricles, cisterns, and sulci are normal, without atrophy, hydrocephalus, midline shift, herniation, or epidural/subdural hematomas. No intracranial hemorrhage or masses. Diffusion-weighted images demonstrate no acute infarct. Cerebellar tonsils are in normal position. Pituitary gland is normal in size. Normal signal flow-void in the superior sagittal sinus, basilar artery, and bilateral internal carotid arteries indicating patency. Postcontrast images demonstrate no enhancing lesions or abnormal leptomeningeal enhancement. Paranasal sinuses and mastoid air cells are clear.

Impressions

1. A few hemosiderin foci involving the left caudate, bilateral frontal, and right temporal lobes, which are similar to the previous study.
2. No acute hemorrhage.
3. No acute infarct, hydrocephalus, midline shift, or herniation.
4. No epidural or subdural hematomas.
